Subsetix: Sparse 2D Geometry on GPU

From Set Algebra to AMR Simulation

Sébastien DUBOIS

HPC@Maths Team

December 2025

Outline

I. Context: GPU & Kokkos

Project Context — Towards Exascale

Background

- **Numpex Project**: French initiative pushing scientific computing to exascale
- **Samurai**: AMR library with unique sparse data structure (interval-based)
- **Challenge**: No prior GPU implementation of Samurai's core concepts

Objective

How can Samurai's strategy evolve for exascale?

- GPU acceleration (today's focus)
- Multi-node distribution (future work)

Approach

Proof of Concept Strategy

1. **Simplify** — Isolate core problems
2. **Prototype** — Build independent bricks
3. **Validate** — Test on real simulations
4. **Integrate** — Path back to Samurai

This work: GPU-native sparse 2D geometry as a standalone proof of concept

GPU Architecture — Massively Parallel

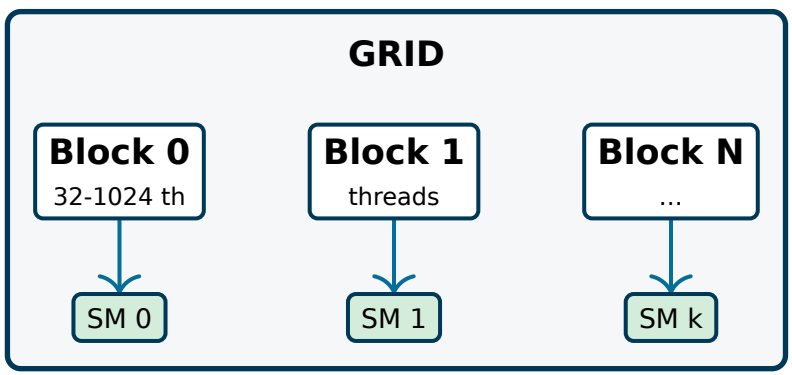
Execution Hierarchy

- **Warp** = 32 threads in **lockstep** (SIMT)
- **SM** = autonomous compute unit
- Multiple warps/SM → latency hiding

For Our Project

- **1 thread** = processes 1 Y row (or 1 cell)
- Thousands of rows → **saturate the GPU**

Execution Model



B200 vs EPYC 9965

	GPU B200	CPU EPYC 9965
Bandwidth	**8 TB/s**	576 GB/s
FP32	**90 TFlops**	14 TFlops

GPU: **14× more bandwidth** than CPU → ideal for large sparse meshes

Kokkos — Performance Portability

The Problem

- CUDA = NVIDIA only
- OpenMP = CPU only (limited GPU)
- HIP = AMD only
- Rewrite for each platform?

The Solution: Kokkos

```
// 1. COUNT — unknown result size
parallel_for(num_rows, KOKKOS_LAMBDA(int r) {
  counts[r] = count_intervals(r);
});
// 2. SCAN — compute offsets
exclusive_scan(counts, row_ptr);
// 3. FILL — parallel write
parallel_for(num_rows, KOKKOS_LAMBDA(int r) {
  fill_intervals(r, &out[row_ptr[r]]);
});
```

CUDA vs Kokkos

Native CUDA

```
double* d_data;
cudaMalloc(&d_data, n*8);

cudaMemcpy(d_data, h_data,
  n*8, HostToDevice);

kernel<<<B,T>>>(d_data, n);

cudaMemcpy(h_data, d_data,
  n*8, DeviceToHost);

cudaFree(d_data);
```

Kokkos

```
View<double*> data("d", n);
auto h = create_mirror_view(data);

deep_copy(data, h);

parallel_for(n, KOKKOS_LAMBDA(int
i){
  data(i) = compute(i);
});

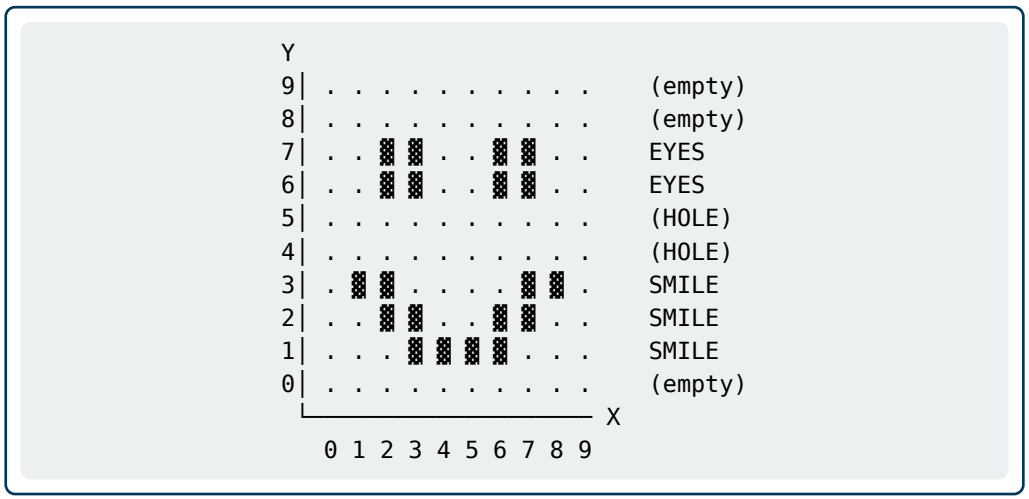
deep_copy(h, data);
// Automatic cleanup (RAII)
```

Single source code → compiles for OpenMP, CUDA, HIP, SYCL, Serial

II. Sparse Representation

Example: 2D Sparse Mesh with Intervals

“Smiley” Geometry :-)



Sparse-CSR-like Representation

```
// 5 rows, HOLE Y=4,5
row_keys = [1, 2, 3, 6, 7]  // skips 4,5!
num_rows = 5

// Rows with 1 or 2 intervals
row_ptr = [0, 1, 3, 5, 7, 9]

intervals = [
  {3, 7},        // Y=1: smile bottom
  {2, 4}, {6, 8},// Y=2: smile thick
  {1, 3}, {7, 9},// Y=3: smile corners
  {2, 4}, {6, 8},// Y=6: EYES bottom
  {2, 4}, {6, 8},// Y=7: EYES top
]
num_intervals = 9

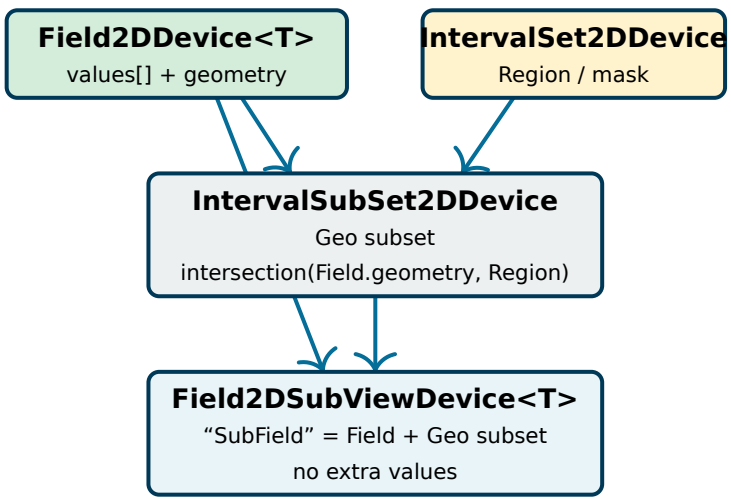
cell_offsets = [0,4,6,8,10,12,14,16,18,20]
total_cells = 20
```

Hole Y=4,5: row_keys jumps from 3 to 6

III. Data Structures

Overview — Device Structures

Core Types



Device-Side Grammar

- `Field2DDevice<T>` = field values + `IntervalSet2DDevice geometry`
- `IntervalSet2DDevice` (region) = mask / target cells
- `IntervalSubSet2DDevice` = geo subset = `geometry ∩ region`
- `Field2DSubViewDevice<T>` = “SubField” = `Field + IntervalSubSet2DDevice`

`Field2DSubViewDevice<T>` internally uses `IntervalSubSet2DDevice`
to iterate only on active cells.

SubField: Usage Example

```
Field2DDevice<Real> rho(fluid_geo);      // Field

// Region = any IntervalSet2DDevice (BC, AMR, overlap)
IntervalSet2DDevice left_bc = make_box_device({0,2,0,ny});

// SubField = rho restricted to left_bc
Field2DSubViewDevice<Real> sub = make_subview(rho, left_bc);

// Apply operations only on this region
fill_subview_device(sub, rho_inlet);
apply_stencil_on_subview_device(sub, bc_stencil);
```

SubView Operations

- `fill_subview_device(sub, val)`
- `scale_subview_device(sub, alpha)`
- `copy_subview_device(dst, src)`
- `apply_stencil_on_subview_device(...)`

In `mach2_cylinder`, overlap/guard regions and AMR masks
use exactly this SubField (SubView) + region mask design.

IntervalSet2D — Complete CSR Structure

Sparse 2D geometry stored as **rows of X-intervals**, indexed by Y coordinate — similar to CSR matrix format.

C++ Definition

```cpp
template<class MemorySpace>
struct IntervalSet2D {
  // Y coordinates of non-empty rows
  View<RowKey2D*> row_keys;  // [num_rows]

  // Index into intervals[] for each row
  View<size_t*> row_ptr;     // [num_rows + 1]

  // All intervals (contiguous)
  View<Interval*> intervals; // [num_intervals]

  // Linear cell offsets
  View<size_t*> cell_offsets;// [num_intervals]

  size_t total_cells;
  int num_rows;
  int num_intervals;
};
```

Basic Types

```cpp
using Coord = std::int32_t;

struct Interval {
  Coord begin = 0;  // Inclusive
  Coord end = 0;    // Exclusive
};

struct RowKey2D {
  Coord y = 0;
};
```

Invariants

- `row_keys` sorted by increasing Y
- Intervals sorted by X within each row
- No overlap between intervals
- `row_ptr[r+1] - row_ptr[r]` = nb intervals row r

Field2D — Field on Sparse Geometry

Associates a **contiguous array of values** with each cell of an IntervalSet2D geometry.

Definition

```
template<class T, class MemorySpace>
struct Field2D {
  IntervalSet2D geometry;  // Geometry ref
  View<T*> values;         // [total_cells]
};
```

Memory Layout

```
Geometry:  ███ ▒ ███ ▒ ████
values[]:  [v0 v1 | v2 v3 | v4 v5 v6]
            ↑       ↑       ↑
offsets:    0       2       4
```

Contiguous values → cache-friendly

Cell Access

```
// O(1) - interval index + x coordinate
T val = field.at(interval_idx, x);
```

Usage

```
Field2DDevice<double> rho(fluid_geo);
fill_field_device(rho, 1.0);
auto rho_host = to_host(rho);  // I/O
```

SubSet — Targeted Region Operations

Represents a **subset of the parent geometry** (intersection with a mask) — used by SubFields to restrict operations to specific cells.

Structure

```
struct IntervalSubSet2D {
  IntervalSet2D parent;  // ref to Field geo
  interval_indices[];    // which intervals
  x_begin[], x_end[];    // restricted range
  row_indices[];         // Y row in parent
  num_entries;
};
```

Usage

```
// Build subset (intersection)
build_interval_subset(
  field.geometry, mask, subset, &ctx);

// Operations on subset only
fill_on_subset(field, subset, 0.0);
```

1D Example: Intersection

```
Parent:  [==A==]   [==B==]   [==C==]
  idx:      0         1         2
          0     8  12    18  22    30

Mask:          [=======M=======]
               5               25

SubSet:        [=]   [==B==]   [=]
               5 8   12    18  22 25
                 ↑       ↑       ↑
entry:           0       1       2
```

SubSet = references to Parent

entry	interval_idx	x_begin	x_end
0	0 (A)	5	8
1	1 (B)	12	18
2	2 (C)	22	25

No data copy — just indices + bounds

⚠ Structure too complex — needs simplification

Field2DSubView — View on Field + Region

Combines a Field with a target region for **localized operations** — lazy intersection, cached for reuse.

Structure

```
struct Field2DSubView<T> {
  Field2D<T> parent;        // ref to field
  IntervalSet2D region;     // where to operate
  IntervalSubSet2D subset;  // lazy intersection
};
```

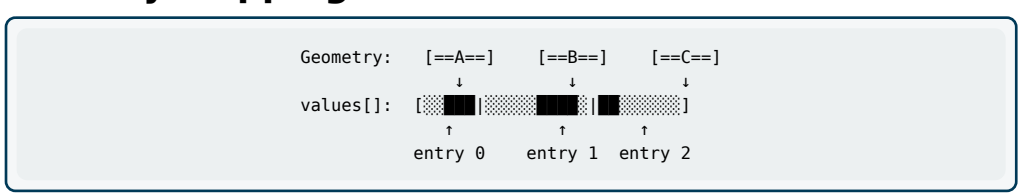
Lazy Pattern

```
// 1. Create (no computation)
Field2DSubViewDevice<T> sub = make_subview(field, region);
// sub.subset is empty

// 2. First op with ctx → triggers build
fill_subview_device(sub, 0.0, &ctx);
// sub.subset = field.geo ∩ region

// 3. Next ops reuse cached subset
scale_subview_device(sub, 2.0);  // fast!
fill_subview_device(sub, 1.0);   // fast!
```

Memory Mapping



▒ = skipped ▉ = accessed by SubSet

Access Formula

`values[ offset[idx] + (x - interval.begin) ]`

O(1) per cell — no coordinate lookup

Workspace & AMR Support

Reusable buffer pool to avoid repeated GPU allocations, and multi-resolution grid structure for AMR.

UnifiedCsrWorkspace

Pool of reusable buffers

```
struct UnifiedCsrWorkspace {
  View<int*> int_bufs_[5];
  View<size_t*> size_t_bufs_[2];
  View<RowKey2D*> row_key_bufs_[2];
  View<Interval*> interval_buf_0;

  auto get_int_buf(int id, size_t n) {
    if (n > int_bufs_[id].extent(0))
      Kokkos::resize(int_bufs_[id], n*1.5);
    return subview(int_bufs_[id], {0,n});
  }
};
```

Avoids repeated GPU allocations
Crucial for chained operations

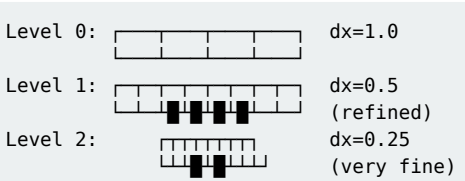
Note: Outputs must be pre-allocated
Use `allocate_interval_set_device()`

MultilevelGeo (AMR)

Multi-resolution grids

```
template<class MemorySpace>
struct MultilevelGeo {
  double origin_x, origin_y;
  double root_dx, root_dy;
  int num_active_levels;
  Array<GeoView, 16> levels;

  double dx_at(int level) {
    return root_dx / (1 << level);
  }
};
```



IV. Algorithms

Binary Search — O(log n) Lookups Everywhere

CSR Requires Sorted Data

All lookups rely on binary search:

1. Find row by Y coordinate

```
int find_row_by_y(row_keys, num_rows, y) {
  // Binary search in row_keys[]
  return lower_bound(row_keys, y);
}
```

O(log R) — R = number of rows

2. Find interval by X coordinate

```
int find_interval_by_x(intervals, begin, end, x) {
  // Binary search in intervals[begin..end]
  return lower_bound(intervals, x);
}
```

O(log I_{row}) — I = intervals in row

Combined: Cell Lookup

```
T& get(Coord x, Coord y) {
  // Step 1: find row
  int row = find_row_by_y(row_keys, y);
  // Step 2: find interval in row
  int iv = find_interval_by_x(
    intervals, row_ptr[row], row_ptr[row+1], x);
  // Step 3: compute offset
  return values[offsets[iv] + (x - intervals[iv].begin)];
}
```

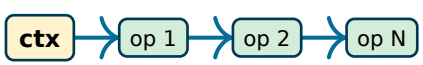
Total: **O(log R + log I)**

GPU: Binary search = suboptimal (future work)

Set Algebra — Binary Operations

CsrSetAlgebraContext

```
struct CsrSetAlgebraContext {
  UnifiedCsrWorkspace workspace;
  // Pool of reusable GPU buffers:
  // - int_bufs_[5], size_t_bufs_[2]
  // - row_key_bufs_[2], interval_buf_
  // Auto-grows on demand, never shrinks
};
```



Same ctx reused → **zero allocations** after warmup

Complete Example

```
CsrSetAlgebraContext ctx;  // create once

auto domain = make_box_device({0,400,0,160});
auto obstacle = make_disk_device({80,80,20});

auto fluid = allocate_interval_set_device(
    domain.num_rows,
    domain.num_intervals + obstacle.num_intervals);

set_difference_device(domain, obstacle, fluid, ctx);
```

Chaining with Buffer Reuse

```
CsrSetAlgebraContext ctx;

// Pre-allocate output buffers ONCE
auto set1 = allocate_interval_set_device(512, 2048);
auto set2 = allocate_interval_set_device(512, 2048);

// Compute: set1 = A ∪ B
set_union_device(A, B, set1, ctx);

// Compute: set2 = set1 \ C
set_difference_device(set1, C, set2, ctx);

// ... use set2 (e.g., create Field2D on it) ...

// Later: reuse same buffers!
set_intersection_device(D, E, set1, ctx);  // set1 reused
set_union_device(set1, F, set2, ctx);      // set2 reused
```

Allocate once → reuse for entire simulation
ctx + set1 + set2: zero GPU malloc in hot loop

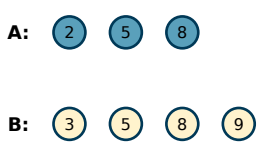
Row Mapping — Why and How

GPU Constraint

1 thread = 1 output row

We need to know output rows **before** parallel processing.

Which Rows Participate?



Op	Output rows	Count
A ∩ B	{5, 8}	2
A ∪ B	{2,3,5,8,9}	5
A \ B	{2}	1

Row Mapping per Operation

Intersection — search smaller in larger

```
parallel_for(n_small, [&](int i) {
  idx_big[i] = find_row_by_y(big, small[i].y);
  flags[i] = (idx_big[i] >= 0) ? 1 : 0;
});
n_out = exclusive_scan(flags, positions);
parallel_for(n_small, [&](int i) {
  if (flags[i]) compact(positions[i], ...);
});
```

Union — bidirectional search + merge

```
parallel_for(n_a, [&](int i) {
  map_a_to_b[i] = find_row_by_y(B, A[i].y);
});
parallel_for(n_b, [&](int j) {
  map_b_to_a[j] = find_row_by_y(A, B[j].y);
  b_only[j] = (map_b_to_a[j] < 0) ? 1 : 0;
});
// Scan + Compact + Interleave A ∪ B-only
```

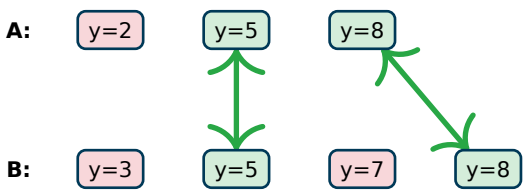
Difference — keep A structure, map to B

```
copy(A.row_keys, out_rows);  // same rows as A
parallel_for(n_a, [&](int ia) {
  idx_a[ia] = ia;  // identity mapping
  idx_b[ia] = find_row_by_y(B, A[ia].y);
  // idx_b < 0 → A-only, no subtraction
  // idx_b >= 0 → must subtract B intervals
});
```

Result: `row_keys` + `idx_a` + `idx_b`
→ enables `parallel_for(num_output_rows, ...)`

Intersection — How It Works

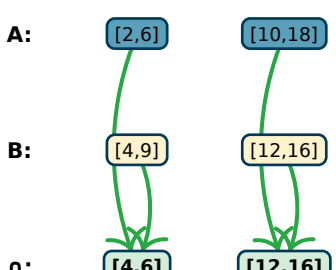
Phase 1: Row Mapping



Binary search: O(log n) per row

Phase 2: Interval Merge (per row)

Row y=5 — 2 intervals each



O(n+m) sweep — `max(begin)`, `min(end)`

GPU Pattern: Count-Scan-Fill

Why? GPU threads can't dynamically allocate — output size must be known before parallel write.

1. COUNT — how many intervals per row?

```
row_counts[i] = count_intersect(A[i], B[i])
```

Parallel per row — don't write yet

2. SCAN — where does each row start?

```
row_ptr = exclusive_scan(row_counts)
```

Prefix sum → row_ptr[i] = write offset

3. FILL — write results at known offsets

```
fill_intersect(A[i], B[i], out, row_ptr[i])
```

Parallel per row — no conflicts!

Same pattern for ∪, \, ⊕

AMR — Restrict & Prolong

Coordinate Mapping (2:1)

Restrict (Fine → Coarse)

```
coarse[x,y] = 0.25 * (
  fine[2x,   2y   ] + fine[2x+1, 2y   ] +
  fine[2x,   2y+1] + fine[2x+1, 2y+1]
);
```

Average of 4 fine cells → 1 coarse cell

Floor/Ceil for Negative Coords

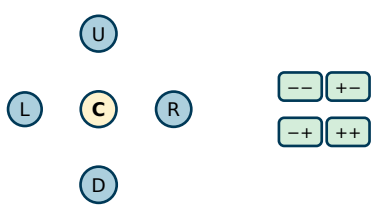
```
// Handles negative coordinates correctly
floor_div2(x) = (x>=0) ? x/2 : (x-1)/2;
ceil_div2(x)  = (x>=0) ? (x+1)/2 : x/2;
// Example: floor_div2(-3) = -2, not -1
```

Prolong (Coarse → Fine)

1. Injection (simple copy)

```
fine[x,y] = coarse[x/2, y/2];
```

2. Linear Prediction (with gradients)



```
grad_x = 0.125 * (R - L);
grad_y = 0.125 * (U - D);
sign_x = (x%2==0) ? -1 : +1;
sign_y = (y%2==0) ? -1 : +1;
fine = C + sign_x*grad_x + sign_y*grad_y;
```

O(1) per cell with pre-computed mapping

Field Operations

Basic Operations

```
// Algebra & reductions
field_add_device(a, b, result);
T dot = field_dot_device(a, b);

// 5-point stencil (W, C, E, S, N)
apply_csr_stencil_on_set_device(
  dst, src, region,
  KOKKOS_LAMBDA(CsrStencilPoint p) {
    return 0.25 * (p.west + p.east
                 + p.south + p.north);
  });
```

AMR: Restrict & Prolong

```
// Fine → Coarse (average 4 cells)
restrict_field_device(fine, coarse);

// Coarse → Fine (interpolation)
prolong_field_device(coarse, fine);
```

Threshold: Field → Geometry

```
// Select cells where |value| > epsilon
IntervalSet2DDevice active =
    threshold_field(field, epsilon);
// Use case: detect shock, refine there
```

Remap: Change Geometry

```
// Project src onto dst geometry
// (overlap → copy, else → default)
remap_field_device(src, dst, default_val);
```

V. Demo

Mach2 Cylinder — Problem & Setup

Description

2D compressible flow simulation:

- **Mach 2** supersonic around a cylinder
- 1st order Godunov scheme + Rusanov flux
- **Dynamic AMR**: 4 levels

Sparse: computation only on fluid cells!

Subsetix Setup

Geometry Construction

```
auto fluid = set_difference_device(
  make_box_device(domain),
  make_disk_device(cylinder), ctx);
```

Conserved Fields (ρ, ρu, ρv, E)

```
ConservedFields U_coarse(coarse_geo);
ConservedFields U_fine(fine_geo);
```

Flux on Coarse Level (excluding fine)

```
auto coarse_active = set_difference_device(
  coarse_geo, fine_projection, ctx);
apply_stencil_on_set_device(
  flux, U_coarse, coarse_active, Flux{});
```

Mach2 Cylinder — AMR Operations

1. Gradient Indicator (detect shock)

```
apply_csr_stencil_on_set_device(
  indicator, U_fine.rho, interior, GradStencil{});
```

2. Threshold → Refinement Mask

```
auto mask = threshold_field(indicator, thresh);
```

3. Expand → Guard Zones

```
expand_device(mask, guard_size, guard_size, fine_geo, ctx);
```

4. Inter-level Transfers

```
restrict_fine_to_coarse(U_coarse, U_fine, overlap);
prolong_guard_from_coarse(U_fine, guard_region, U_coarse);
```

5. Intersect → Overlap Region

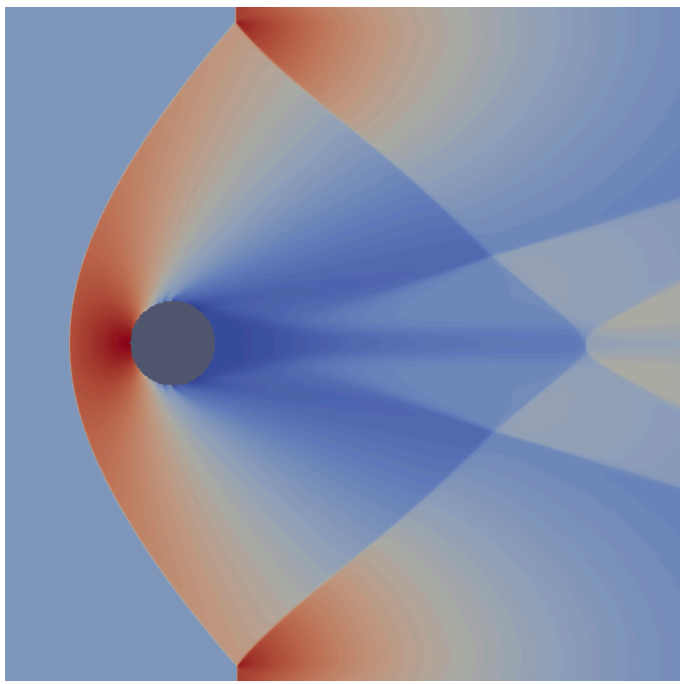
```
auto overlap = intersect_device(
  coarse_geo, fine_geo, ctx);
```

6. Union → Merge Geometries

```
auto all_refined = union_device(
  mask_level1, mask_level2, ctx);
```

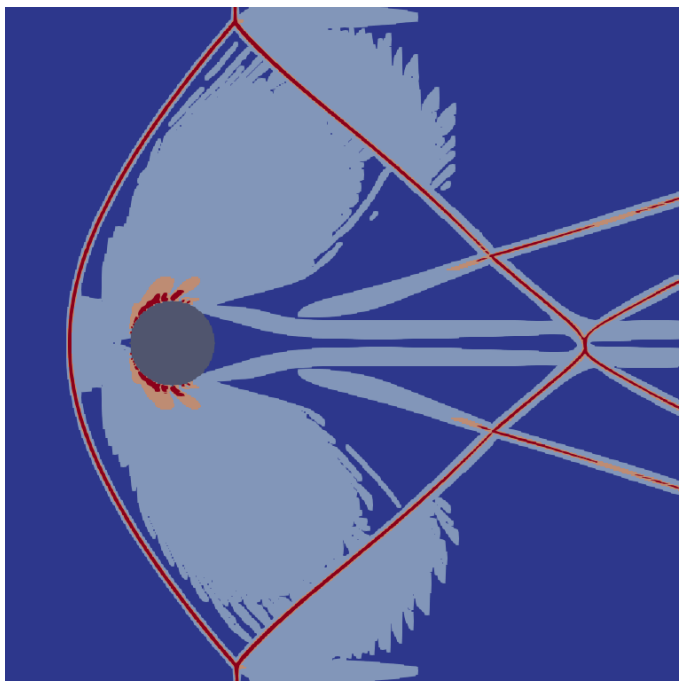
Mach2 Cylinder — Visual Results

Density Field



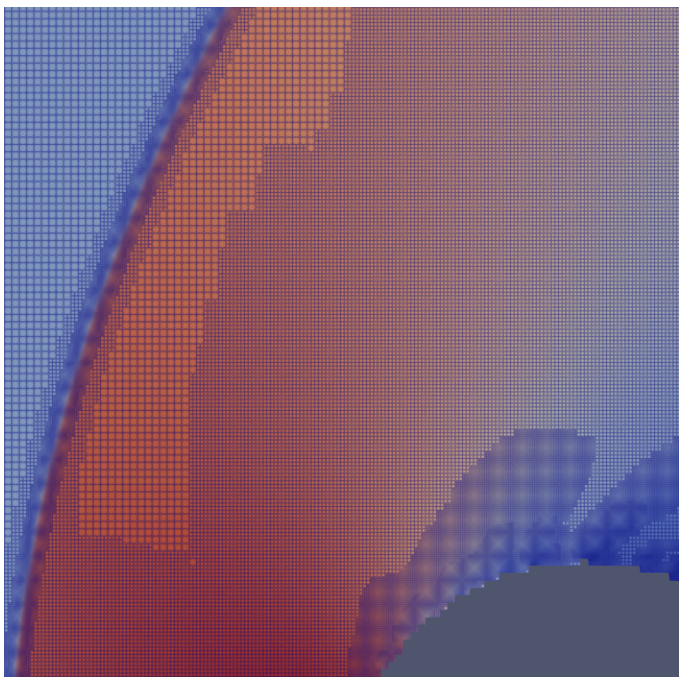
Bow shock in front of cylinder
Colormap: blue (low) → red (high)

AMR Levels



Automatic refinement zones
near the shock front

Mesh Zoom



Multi-level AMR resolution
near the bow shock

4 AMR levels (9–12) — Automatic refinement based on density gradient

Thank You!

Questions?

Key Points

- CSR interval representation
- Count-Scan-Fill pattern
- Kokkos parallelism (CPU/GPU)
- Workspace for memory reuse
- Multi-level AMR (Mach2)

Appendices

Appendix A: Project Evolution

Implementation History

Version	Description	Performance	Status
v1	CPU only, Sparse CSR + Workspaces First sequential implementation	Faster than baseline	✓ Stable
v2	Multithreaded **Tiled** Sparse CSR OpenMP and TBB backends Tiling for locality	Excellent on large mesh	⚠ Complex Likely bugs
v3	CUDA only GPU set algebra Proof of concept	**Fastest**	✓ PoC validated
v4	**Kokkos** (current version) Non-tiled Sparse CSR OpenMP + CUDA portability	Slower than v2/v3	✓✓ **Reliable** Verified

Lessons Learned

- **Tiling** improves locality but greatly increases complexity
- Native CUDA faster but less portable
- Kokkos = best **reliability/portability** tradeoff

Final Choice: Kokkos

- **Single** code for CPU and GPU
- Simplified maintenance
- Easy testing and verification
- Active ecosystem (Sandia, Trilinos)

Appendix B: Why Kokkos?

Comparison with Native CUDA

Aspect	CUDA	Kokkos
Portability	NVIDIA only	**Multi-vendor**
Syntax	<<<>>>	**C++ standard**
Memory	cudaMalloc	**View<T*>**
CPU Debug	Difficult	**Easy (Serial)**
Maintenance	Duplicated code	**Single code**
Performance	**Optimal**	90-95%

Supported Backends

- **OpenMP**: CPU multi-thread
- **CUDA**: NVIDIA GPU
- **HIP**: AMD GPU
- **SYCL**: Intel GPU
- **Serial**: debug and tests

Benefits for This Project

1. Faster Development
Debug on CPU (Serial/OpenMP), deploy on GPU

2. Reliable Tests
Same code tested on CPU and GPU
No hidden “GPU-only” bugs

3. Std Algorithms
`transform`, `reduce`, `scan`, `copy`...
Familiar API, platform-optimized

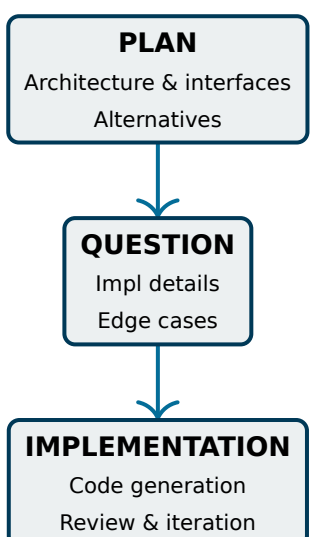
4. Ecosystem
Trilinos, ArborX, Cabana...
Sandia National Labs support

Appendix C: Development Methodology

Models Used

- **Claude 4.5 Opus** (Anthropic)
- **Claude 4.5 Sonnet** (Anthropic)
- **gpt-5.1-codex-max** (OpenAI)

Work Pattern



Observed Benefits

- **Rapid exploration** of designs
- Generated inline documentation
- Automatically suggested tests
- Assisted refactoring

Points of Attention

- Systematic code verification
- LLMs can hallucinate APIs
- Always compile and test
- Maintain **architectural control**

LLM = **accelerator**, not replacement
Human expertise remains essential
